

Remediation on the former uranium mining and milling site (Hungary): Case Study

M. Csővari

The presented work is a common work of the experts from MECSEK-ÖKO Rt, Pécs, Hungary and MECSEKÉRC Rt, Pécs, Hungary and other companies, institutions

„DIFPOLMINE” CONFERENCE Budapest
4-8 July 2005

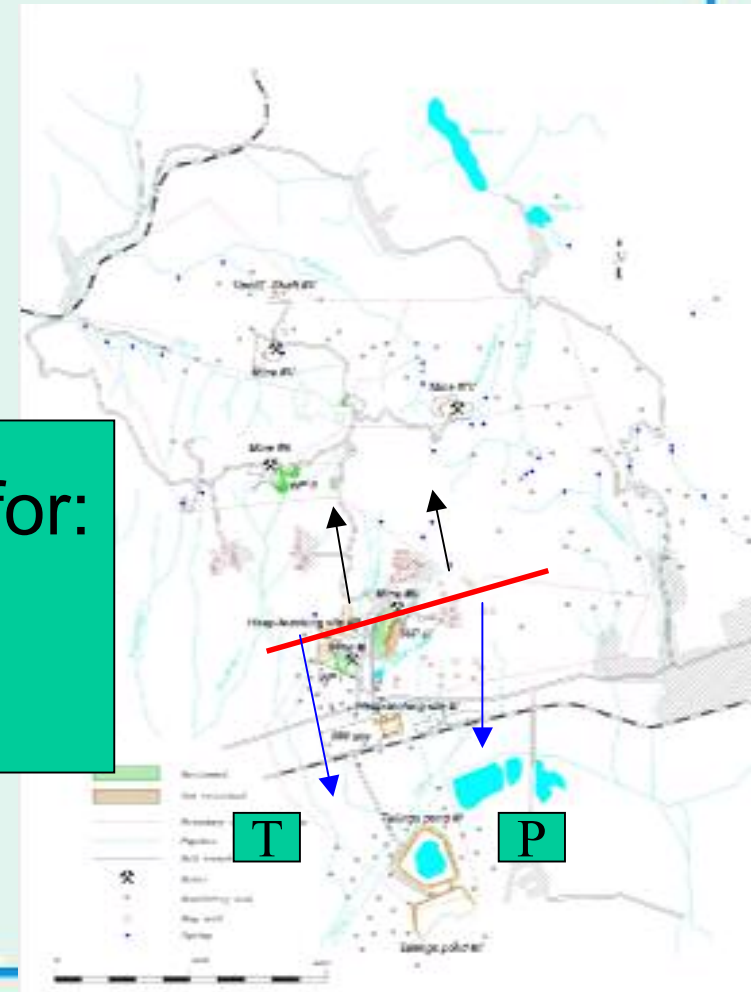

Location of the site

The site has a close connection with **drinking water** catchement areas (T and P).

Water treatment is necessary for:
Mine water
Contaminated groundwater

Geological cross-section of the former mining site (Western Mecsek)

Water treatment processes

1) Mine water treatment

Anion-exchange process is used for U
(TDS~1.6 g/l; U~5 mg/l; As<12 mg/l, Ra~0.3 Bq/l)

2) Groundwater treatment

Pump and treat process

(TDS~3-15 g/l; U<0.1 mg/l; Ra~0.08 Bq/l)

Heavy metals:As<12 mg/l;

Pilot-scale PRB (ZVI + sand mixture)

(in situ groundwater treatment, experiment)

I Mine water treatment station

Station is situated on the area of former Shaft NI

Yellow cake production

Precipitation of uranium peroxide

Packing unit

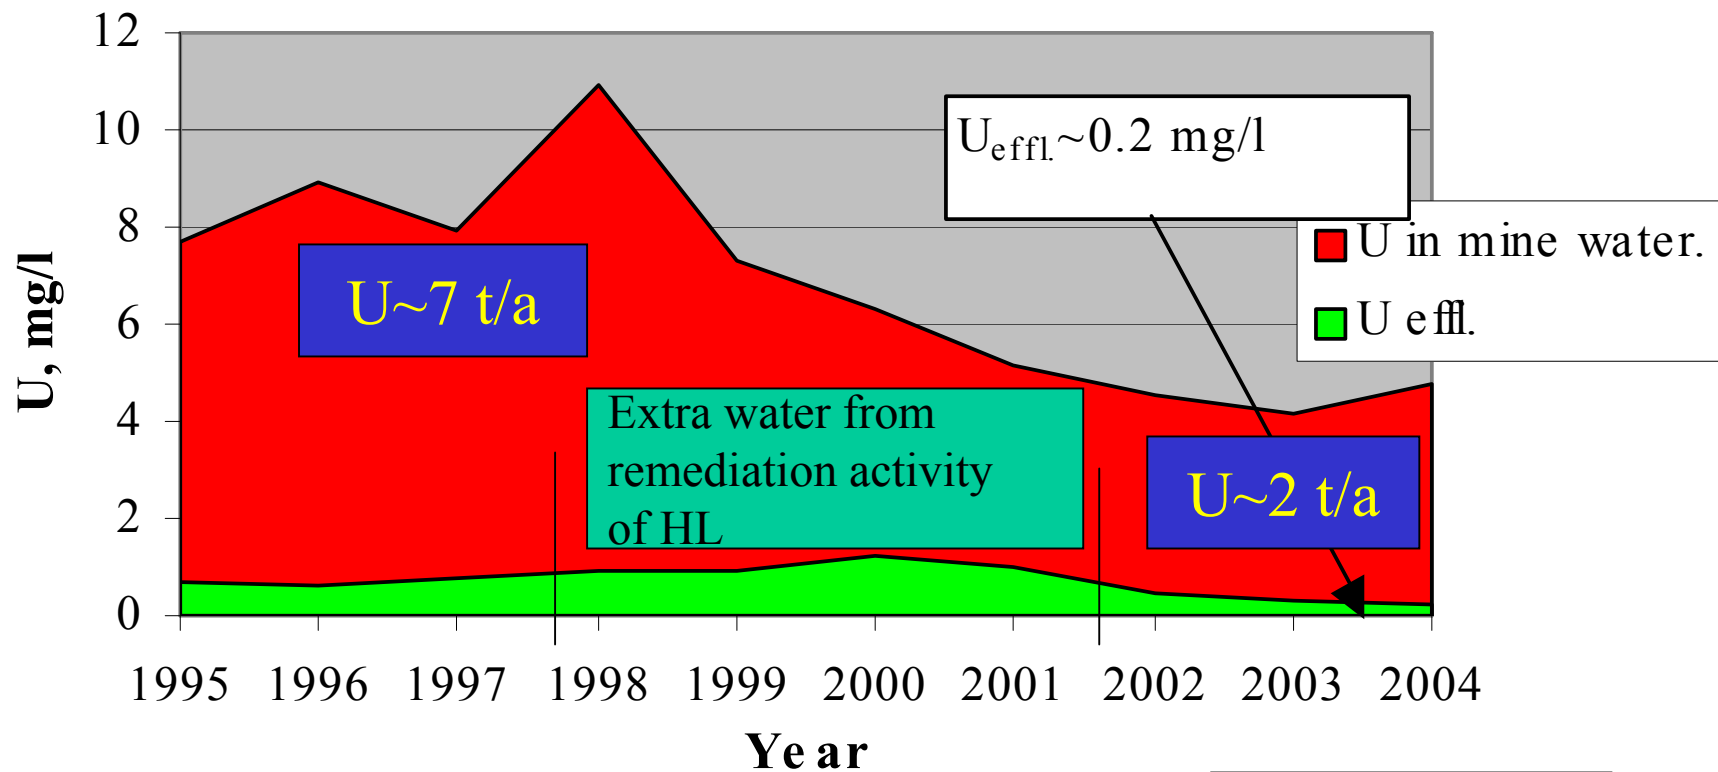

B

U-concentrate accretion on the mixer in dryer causes some problems

Mine water treatment

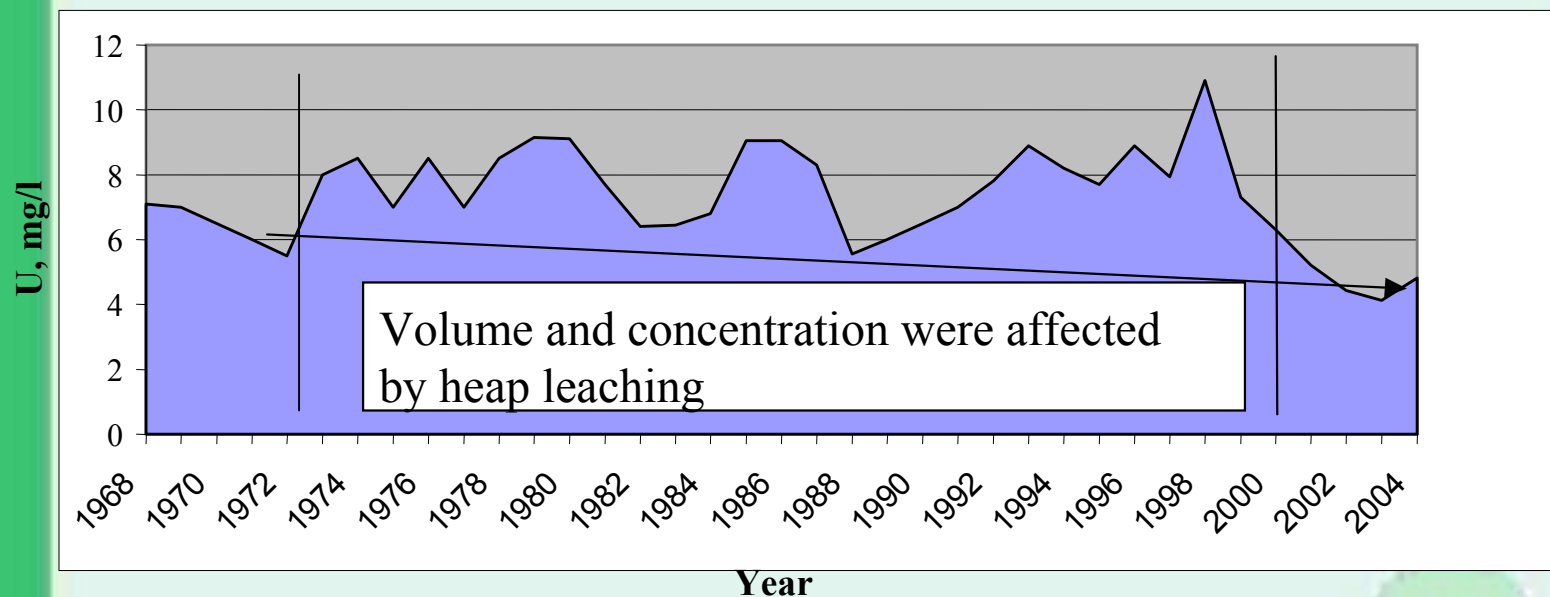

Sorption efficiency for uranium

$V \sim 1.2 \text{ Mm}^3/\text{a}$

$V \sim 0.44 \text{ Mm}^3/\text{a}$

The change of uranium concentration in mine water over long period (1968-2005)

6-7 mg/l $\xrightarrow{35 \text{ years}}$ 4.5-5 mg/l

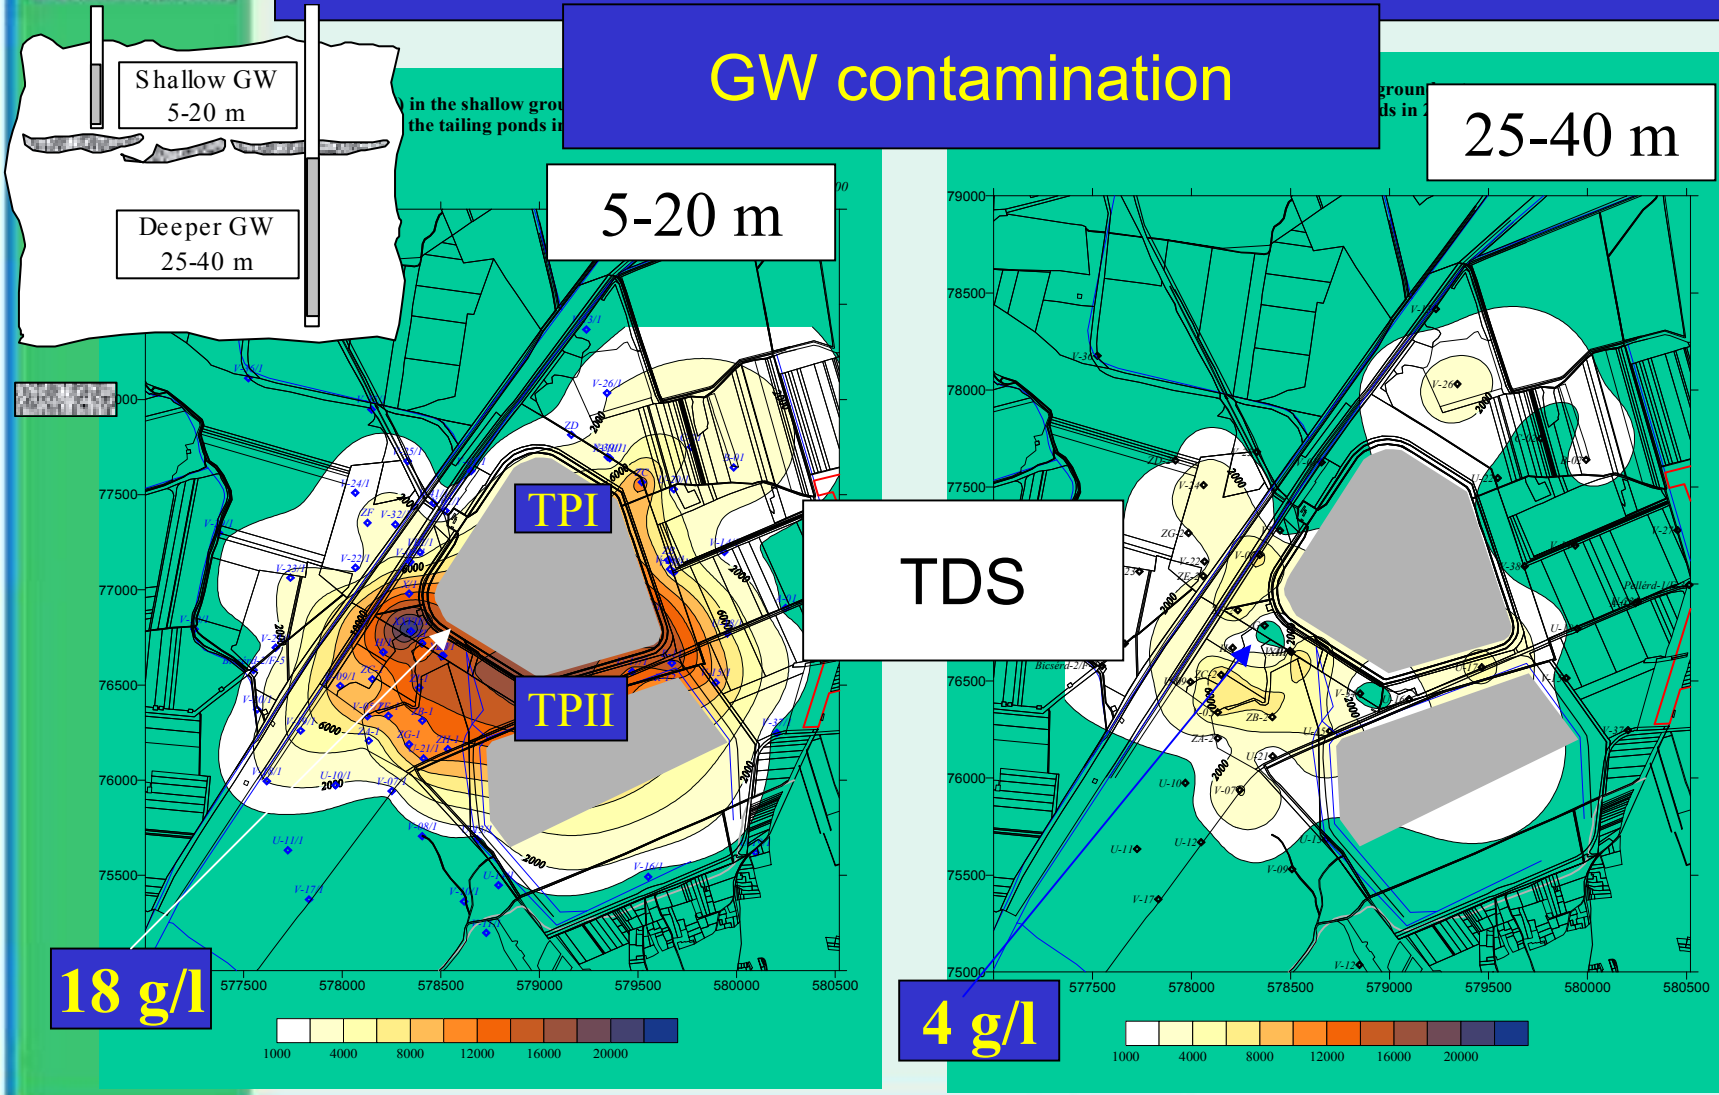

II Groundwater treatment Tailings Ponds

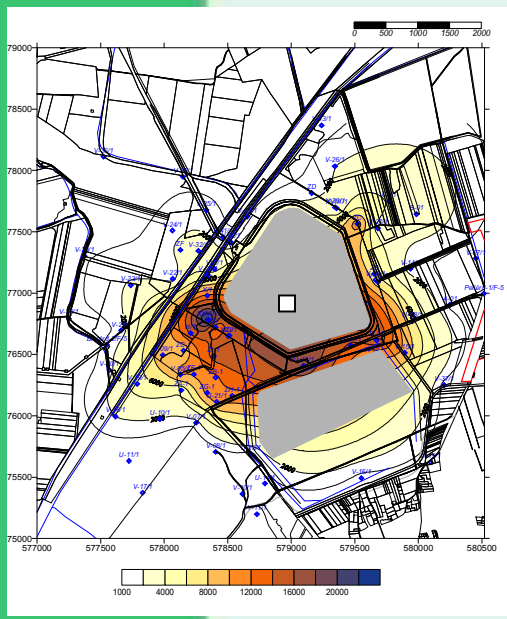

Total volume of the tailings:
20.4 kt solid + 32 Mm³ of liquid

Groundwater restoration

GW contamination

Groundwater contamination under the TP

Groundwater treatment process

Shallow GW: TDS~10-12 g/l

For treatment

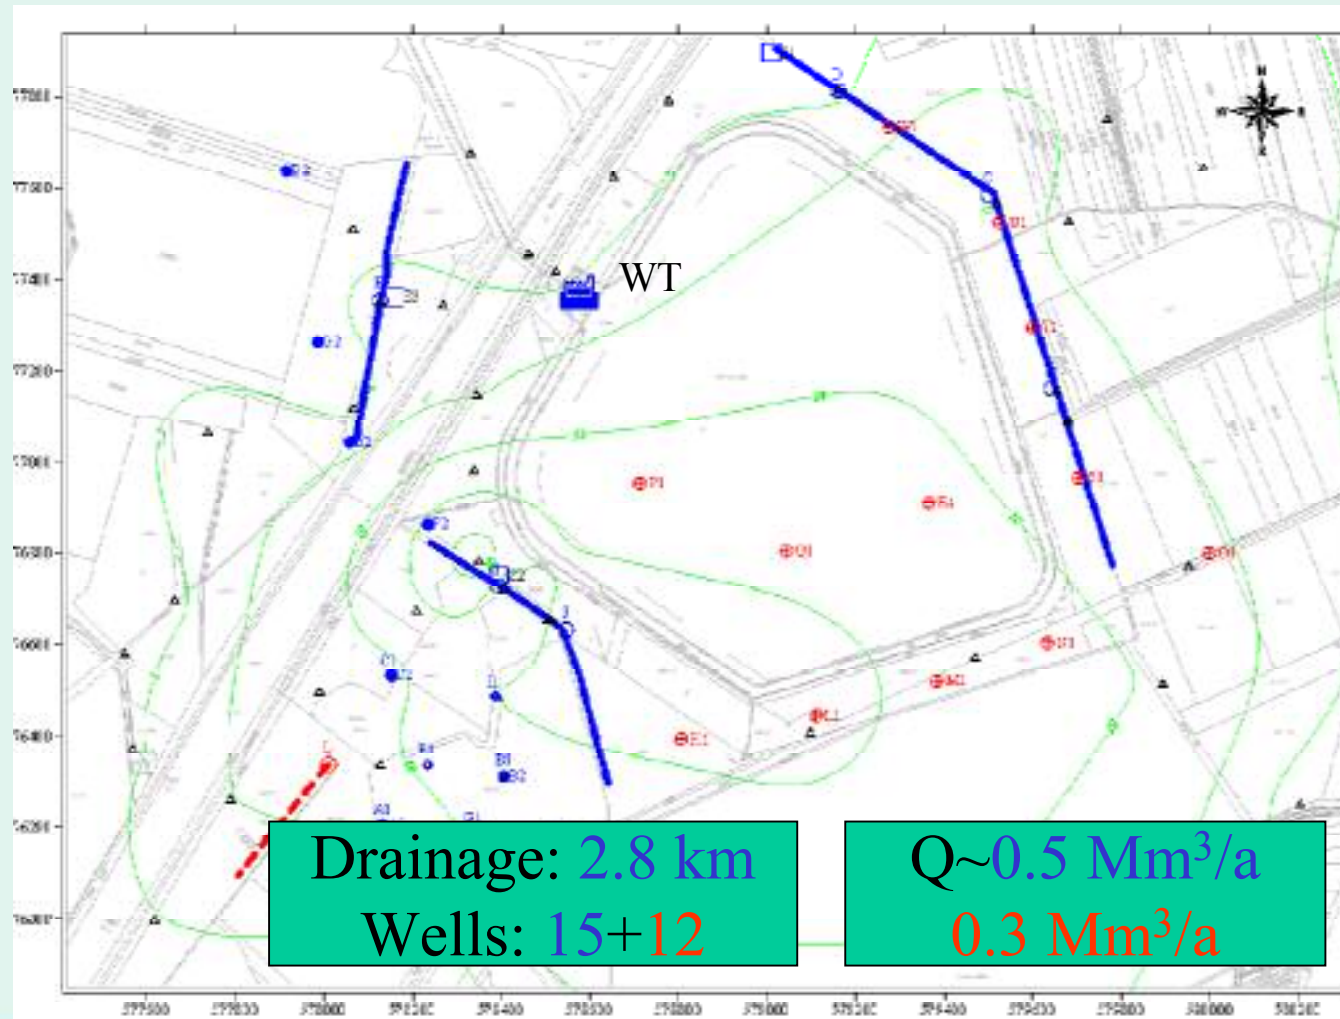

Deeper GW : TDS~3-5 g/l

Direct discharge

Treatment process consist of:

- Precipitation of magnesium and gypsum with calcium hydroxide
- Sedimentation and thickening
- Filtration

Groundwater extraction system

Sludge from treatment

Sludge
7kt/a (with 50% water content)

Treated water: ~0.36 Mm³/a

TDS ~6-7 g/l (retention time!!)
(NaCl ~3 g/l)

Mg ~17%
Ca ~17%
SO₄ ~26%
U ~60-70 g/t
Ra ~24 Bq/kg

Gypsum accretion on the surface of technological equipment

**Critical parts and units must be
monthly cleaned from
gypsum accretion**

Water discharge summary

Treated groundwater

V:0.36 Mm³

Treated mine water

V:0.44 Mm³

Mixing basin

TDS:3.2 g/l

U:0.2 mg/l

Ra:0.18 Bq/l

Non-treated
water

(e.g.deeper GW)

V:1.27 Mm³

Receiver

Data for 2004

III Pilot-scale PRB (for in situ treatment of GW)

Field test aiming at investigating of long-term performance of PRB (EU project: EVKI-1999-00035) for removing of U from GW

Practical solutions are known in first of all in USA , but the long-term performance is still under investigation

For field test ZVI+sand mixture was selected, though different reactive materials were tested in laboratory and in **columns on the field**

Permeable reactive barriers

Permeable reactive barriers

Landfill Liner

Trench and Fill

Funnel and gate system

Uranium contaminated groundwater In valley Zsid

Valley

Valley Zsid

■ Monitoring well Hb1/1

Slite contamination of GW was detected in GW on the site

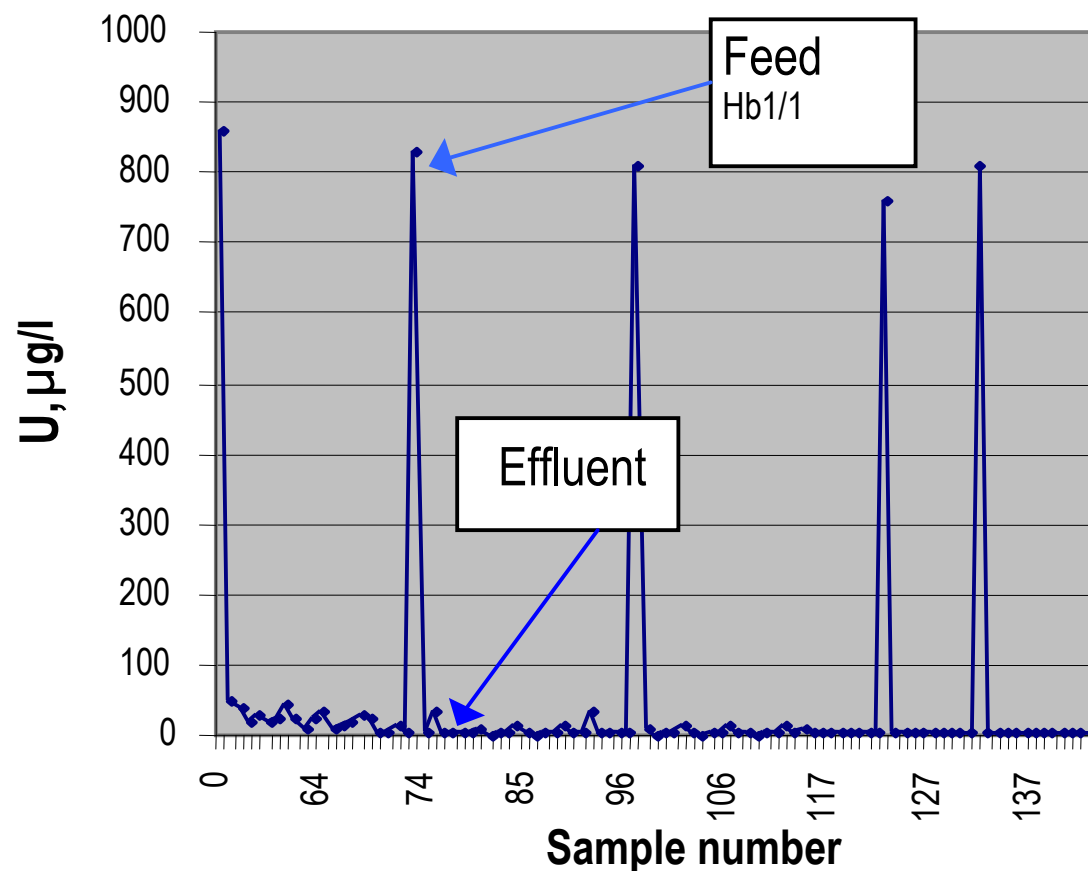

Laboratory experiments in columns

**Iron, hydroxiapatite,
anion exchange resin,
etc. were tested**

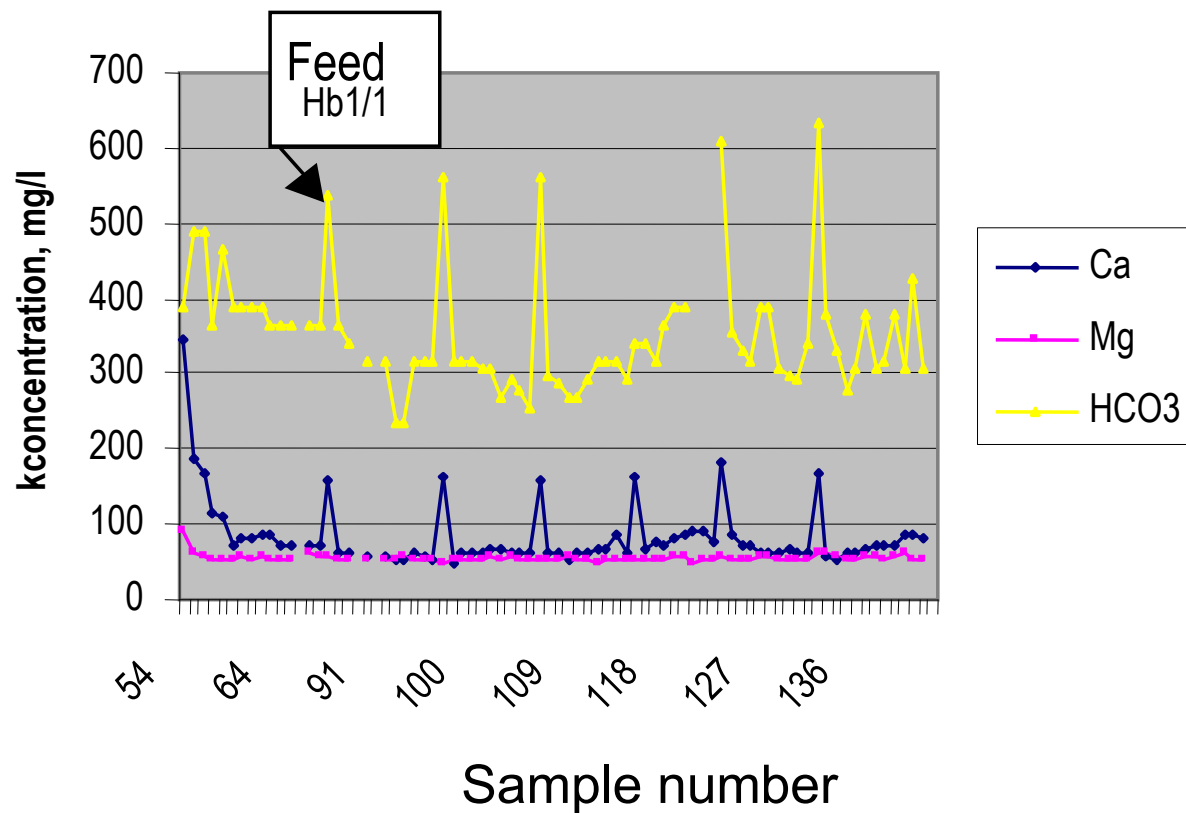

Removal of uranium from contaminated GW

Uranium can be removed from GW by steel fibres

Changing the general chemistry of water

Bycarbonate calcium etc. Are dropps during treatment

Colomns in monitoring wells

Field column experiments

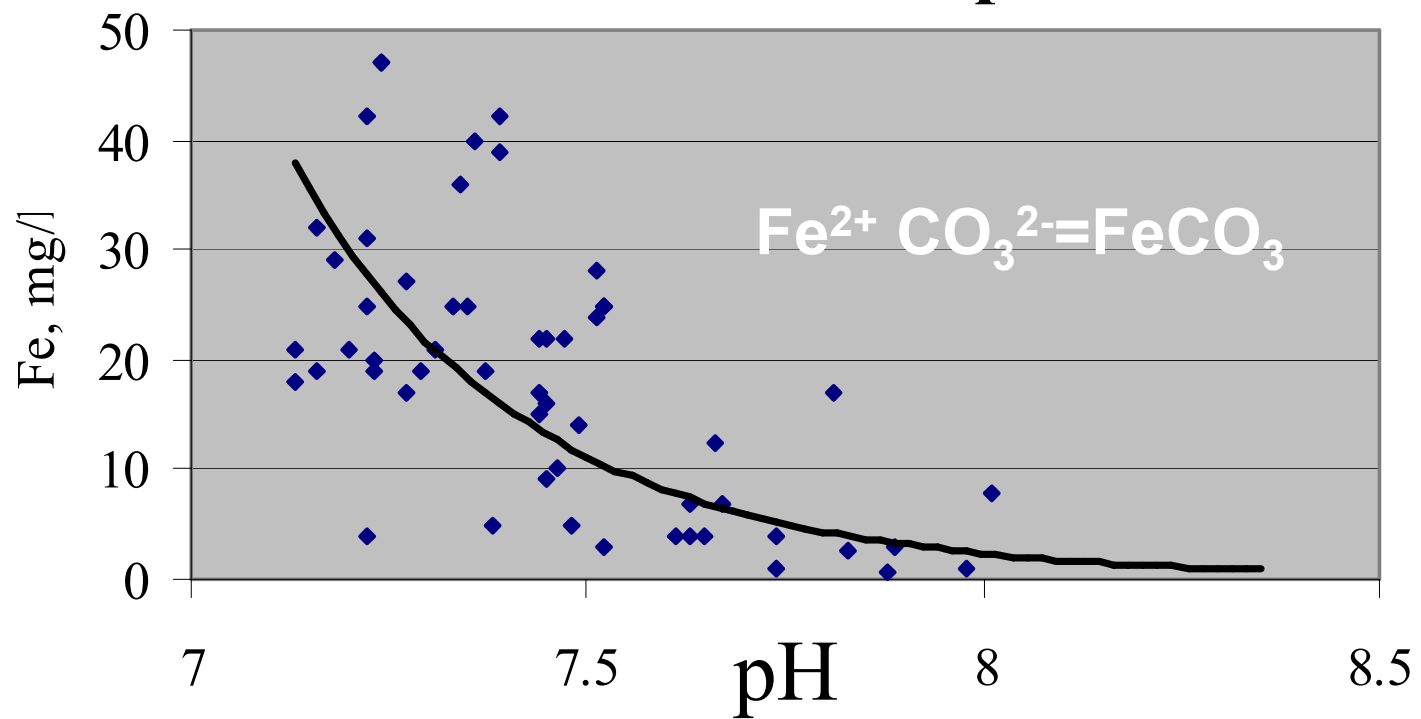

Geochemical processes controlling GW chemistry

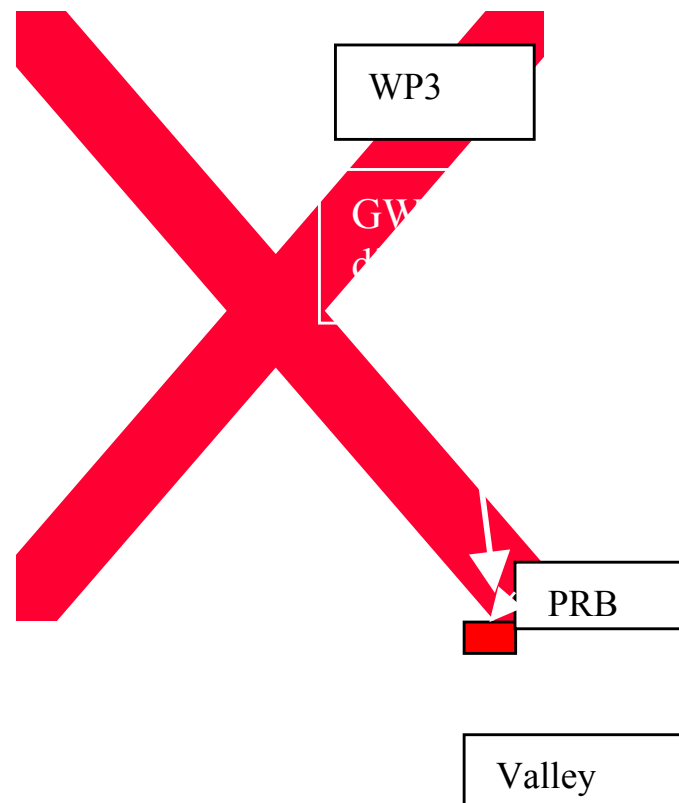

Geochemical processes in GW

Iron concentration vs. pH

Location of the PRB

The installation is located in a narrow valley at the foot of WPIII, linking the mining area with drinking water aquifer (*Zsid-valley*)

Principal design of the experimental PRB

Elemental iron mixed with sand

Spec. Surface:
0.7 m²/g

0.2-3 mm

Construction of the PRB

Permian sandstone with
sediments

Two layers of
Fe+sand mixture

Monitoring wells placed in reactive zones

Construction of the PRB

Design of experimental Permeable Reactive Barrier

Length: 6.8 m;
Depth: 3.9 m
Width: 1.5m;
Two zones;
G: 39 t ZVI (mixed with sand)

PRB with monitoring wells

**28 monitoring
wells**

Precipitation of uranium and dissolution of iron

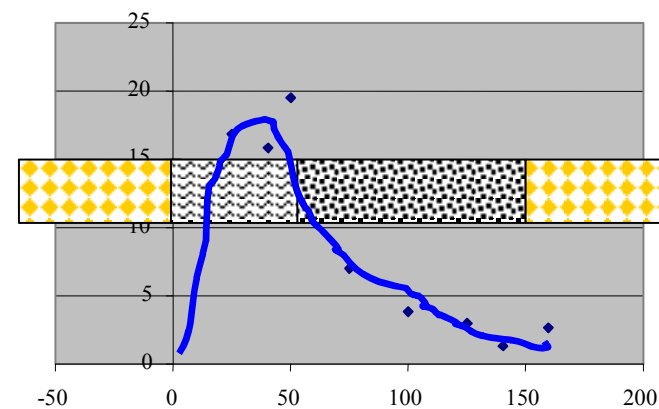

Uranium concentration profile in the PRB

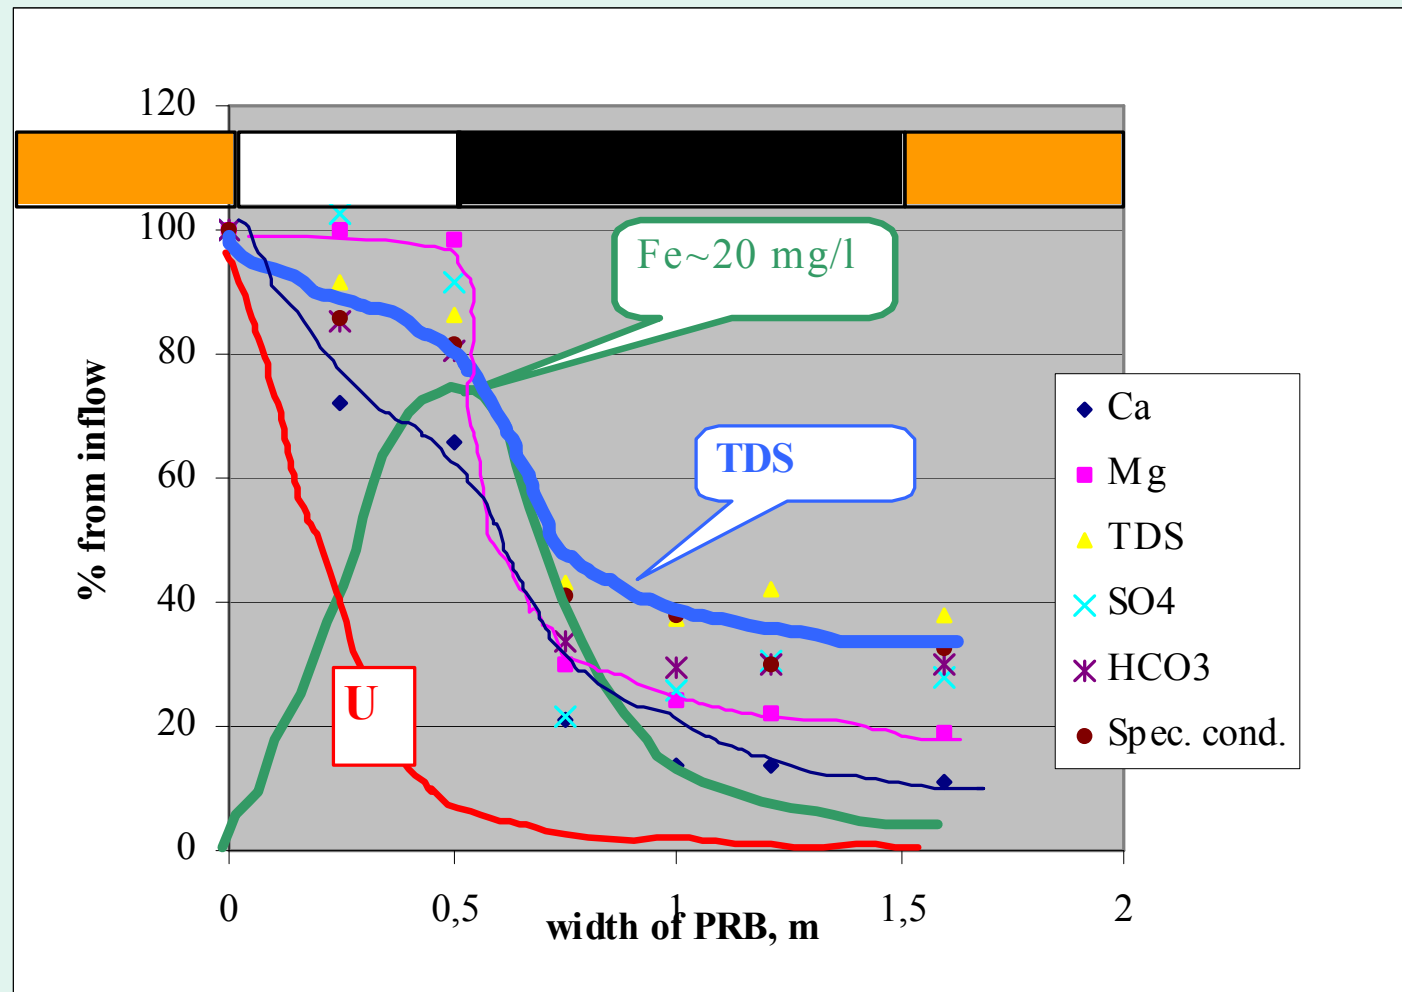

Iron first dissolves
in first zone
than precipitates
in the 2nd zone

Uranium conc. drops in
the first zone

Iron concentration profile in the PRB

Concentration profiles in zones of PRB

PRB performance (August 2002-April 2005)

GW flow direction

	pH	EC μS/cm	U(VI) μg/l	TDS	Ca	SO ₄	HCO ₃	Fe
				mg/l				
Inflow	6.9	1400	940	1010	150	320	525	0.002
Zone I	7.3	1330	37	937	125	300	275	5.5
Zone II	8.7	865	10	550	10	185	299	0.03

Uranium is removed with high efficiency but huge volume of inert compounds (CaCO₃, MgCO₃ etc.) is precipitated

Isolines of uranium and calcium concentrations on the test field

V.7 Development of uranium concentration in downstream monitoring well

Performance change

Water passed through the PRB: $\sim 700 \text{ m}^3/\text{a}$
Formed precipitate: $\sim 0.5 \text{ kg/m}^3 \sim 350 \text{ kg/a}$
Free porosity in PRB (original) $\sim 11 \text{ m}^3$
Annual losses: $\sim 0.35 \times 2.7 \sim 0.094 \text{ m}^3$
in percentage: $\sim 1-1.5\%$

Iron dissolution: $\sim 20-30 \text{ mg/l Fe(II)}$
 $G = \sim 700 \times 0.03 = 21 \text{ kg/a}$

Performance monitoring is continued

- by regular water sampling
- by planned drillings
- by hydrogeological evaluation

Acknowledgement

**The research works related to the GW
treatment was
supported by the IAEA (Contract: N^o 9114).**

**The research related to the PRB and dispersion
of contaminants under TPs was partially supported
by EU
(Contract: EVIKI-1999-00186 and EVGI-CT-2002-00035)**

Precipitation of gypsum and magnesium

Kinetic curves of the precipitation of magnesium hydroxide and gypsum

I.3 Project cost distribution
