

Natural susceptibility to compaction

This map shows the natural susceptibility of agricultural soils to compaction if they were to be exposed to compaction. The evaluated soil's natural susceptibility is based on the creation of logical connections between relevant parameters (soil database rules). The input parameters for these pedotransfer rules are taken from the attributes of the European soil database, e.g. soil properties: type, texture and water regime, depth to textural change and the limitations of the soil for agricultural use. Besides the main parameter, auxiliary parameters have been used as impermeable layer, depth of an obstacle to roots, water management system, dominant land use and secondary land use. It was assumed that every soil, as a porous medium, can be compacted.

MAP INFORMATION

Spatial coverage: 27 Member States of the European Union where data available.

Pixel size: 1km

Projection: ETRS89 Lambert Azimuthal Equal Area

Input data - source
Soildata - European Soil Database v2
Land Use - CORINE Land Cover 2000
